Lighting

EL Zone Exposure System- how does it work and how do you use it

Lighting Reviewing

BY MATTHEW ALLARD JNR 6 YEARS AGO 22 MIN

EL Zone is an exposure tool that is based on stop values that make sure no one ever has to guess what exposure they are using ever again. It's a tool I thought that I'd see worth looking into in more detail.

What is the EL Zone exposure system?

The EL Zone exposure system which was designed by cinematographer Ed Lachman, ASC, is an innovative tool for helping to expose cameras when using shops. EL Zone is a system that is designed to help you achieve the highest precision, greater consistency, and more intuitive on set camera choices.

EL Zone can be found on Cinelab's monitors that are running the latest Cinelab's firmware update. EL Zone is also available for monitoring using a waveform monitor or a vig scope. It doesn't work if you are hoping a signal with a LUT or Look enabled.

How is it different from False Color?

False color will assist exposure but it only works on a single camera, which tracks percentages in voltage. False color works by comparing the relative luminance values of the image and then assigning a false color to represent a specific range of values in IRE or %. The IRE scale false color was developed way back in the 1950s by The Institute of Radio Engineers.

The problem with false color on most monitors is that it isn't mapped to any particular camera and nothing is standardized. Different monitors and cameras show false color in different ways.

I have constantly complained about this for years. So many monitors that get released with false color, and I'm sure that I'm not the only one who feels this way, but it's not mapped specifically to individual cameras and looks different on different cases and scales. Different cameras have different IRE values for various exposure points. Monitors running false color don't take this into consideration. Cinelab's monitors are running exposure choices based on false color but only can be accurate. For a camera like the Alexa 35 where the IRE value for middle grey is 28%, you are not going to get an accurate exposure reading because the system is based to just assuming that middle grey should be somewhere around 42-43 IRE.

Above is a prime example of what I am talking about. Let's compare the false color on the Cinelab monitor to the Sony BVM-HX310 monitor. The Sony monitor is set to 709 being fed the exact same signal. As you can see, the Cinelab is set to look a bit like ARRI, but the Sony it is showing me colors that are completely different. This is where the problem lies. Cinelab's monitors are great, but the false color system is not going to become confusing for the end user. This is where you want the false color to help you if you are seeing on your camera to match the false color you are seeing on your monitor.

This is new, false color, regardless of how it is being displayed, is still going to get you in the ballpark, and for a lot of users, close enough is good enough. If you have a Cinelab monitor, you can use EL Zone and know the basic facts. Personally, I have a big issue because it has been mapped to our cameras.

At least on monitors from SmallHD, you can set up your own false color scale or you can use the one mapped HDR one which is what I like to use. Every one of our monitor that hasn't been mapped to a particular camera is not ideal. If you own or use one of these, I'd suggest that you get in contact with Cinelab and see if you can get them to do it or you using a bit of the monitors measurements. Rant it and it be accurate as you think. In saying that it really does depend on the camera. Because a lot of cameras like the Alexa 35 have a middle grey value that is not 42-43 IRE and if you use a camera regardless of what false color system is being used.

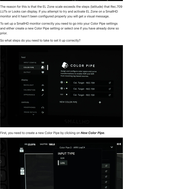
EL Zone is a system based on 18% grey, which is a universal standard for measurement. Skin tones are also based on this value. Skin tones are also based on exposure tolerance as they will be consistent with each other. One of the nice aspects of EL Zone is that you can take a frame grab of a scene to precisely match exposure from one camera to the next if you need to do any matching work eg., maintain consistency, or for VFX work.

What cameras & equipment utilize EL Zone?

Maybe a lot of our readers won't know this, but EL Zone was incorporated into the Panasonic VariCam LT and VariCam 35 cameras with the latest firmware update (V9). To my knowledge, these are the only cameras that currently utilize EL Zone, apart from the Sigma fp and fp L which received the feature just recently in a firmware update. Panasonic has also released a guide to EL Zone for their cameras. I don't think that adoption is going to continue and I think we may well find more cameras and software starting to use it in the future.

So how do you use EL Zone?

EL Zone has 15 delineated zones in +5 increments above +5 = % increments above 100% and 5 stops of stops below 0% = % increments below 0%.



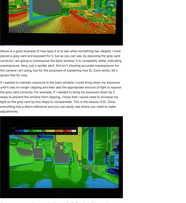
Each stop or zone is displayed as a solid color which makes it very easy to identify the exact stop value. This makes it more precise than false color because you are seeing a specific percentage value. This is why I think it is a great tool for anyone who is looking for a setting middle grey, skin tones, and displaying if anything is being clipped. It doesn't offer as much information as EL Zone does.

Cinelab's false color system is based on a 10 stop system that includes light level distribution in zones. I like how this has been implemented because the values make sense. While for overexposure, black for under exposure, and grey for 18% grey.

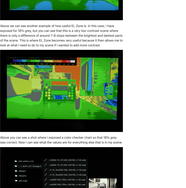
As I mentioned earlier, an SmallHD monitors you have to send the monitor a Log signal without a LUT or look applied. This is the only way to make sure you need to make sure that the SDI or HDMI output is sending out a Log image.

The reason for this is that the EL Zone scale exceeds the steps (latitude) that Rec 709 LUTs or Look can display. If you attempt to try and activate EL Zone on a 709 monitor and it hasn't been configured properly you will get a visual message.

The next step is to set the **Input Type** to **LOG**.



The Pilot editor for camera type you are using, in this case, because it is the Alexa 35 I select **ARRI** and then I set the **Color Space** to **ARRI Wide Gamut 4** and the **Gamma** to **LogC4**.



I have now set up my Color Pipe correctly to use my camera with EL Zone on a SmallHD monitor. Once the Color Pipe has been created it will be automatically saved to the Pilot. You can create multiple Color Pipes and change them around and then assigning a camera you are happier to be using.

The only slight caveat with this process is that you can't just send a signal out from your camera that has a look or LUT applied to it via EL Zone to work, as I pointed out mentioned, it needs a Log image. What this essentially means is that you need to have a Log signal out of the box and the monitor that you are using in your camera what you are not using EL Zone.

Now, when you activate your **Exposure Assist** on a SmallHD monitor and choose **EL Zone** you will see the screen that is above. On the screen, it is a good idea to select **Hide Color Scale** so you get a clear reference for what you are seeing.

Or once Stage, you will then be able to see the Color Scale and what the color values represent. In the example above you can see that in this shot there are about 10 stops. The Color Scale represents the following values: Black, Purple, Blue, Back Swing, 18 stops below middle grey, and red being +5 stops above middle grey.

Above is a good example of how easy it is to see when something has clipped. I have placed a grey card and exposed for it, but as you can see, by exposing the grey card correctly I am going to overexpose the back window. It is completely white, indicating that it has clipped and is overexposed. Now I could have underexposed and kept the window I was not using, but for the purposes of explaining how EL Zone works, let's ignore that for now.

I have underexposed exposure in the back window I could bring down my exposure until it was no longer clipping and then add the appropriate amount of light to expose the grey card correctly. For example, if I needed to bring my exposure down by 2 stops to preserve the window from clipping, I know that I would need to increase my light on the grey card by two stops to compensate. This is the beauty of EL Zone, it makes exposure much more reference and you can easily see where you need to make adjustments.

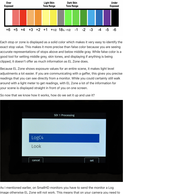
Above we can see another example of how useful EL Zone is. In this case, I have underexposed the grey card by 2 stops and you can see that it is now sitting at 18%. There is a big difference of around 7-8 stops between the brightest and darkest parts of the scene. This is where EL Zone becomes very useful because it then allows me to look at what I need to do to my scene if I wanted to add more contrast.

Above you can see a shot where I exposed a color checker chart so that 18% grey was correctly set. Now I can see that the values are the following that is in the scene.

Now, to check how well using EL Zone is working, let's turn it off after we have set our exposure and then added a LUT.

So what did we get? Well, as you can see, we got a well-exposed image.

So how do you accurately expose for skin tones?



Caucasian skin is represented by either medium yellow (+10 stop over 18% grey), or bright yellow (+15 above 18% grey).

Dark skin is represented by light green (-10 stop below 18% grey), or medium green (-5 stop below 18% grey).

Now, the only problem with EL Zone is that it does take a while to get your head around it if you are used to using false colors. As your brain gets pre-mapped with what false color values are indicated so you need to re-train it to use EL Zone.

How does it compare to using False Color?

I wanted to do some testing to see if there were exposure differences between using EL Zone and false color and if there were any issues in using it.

Above you can see the images for a scene with a color checker chart where exposure was set to 0 Zone.

Now, let's expose the same exact same shot using false color.

If we look at both images after exposure was set they are pretty close, although I think using the EL Zone method provided a slightly better result.

Now, the only problem with EL Zone is that it is limited to 18 stops, but if we go to the Camera Raw Settings in Photoshop, we can see that the Exposure slider has a range of +/- 5 EV while thanks to EL you won't be able to see an accurate representation of all of your stops. With false color in the camera, I can have it applied to Log image so that I can see the entire dynamic range of the camera. Then I can adjust my exposure so that I can count my exposure before I get any clipping. This is something you can't do with EL Zone because it is going to show overexposure well before my image has actually clipped.

I will show you what I mean. Above is an image where EL Zone is showing overexposure in the scene.

However, if we use false color for the exact same image with the exact same exposure settings you can see a massive difference. There are no overexposed parts of the image, in fact, nothing comes even remotely close to clipping.

EL Zone has to be calibrated specifically to each specific camera sensor's gamma and outputs. In the Panasonic Varicam and Varicam LT, as well as the Sigma fp and fp L, EL Zone is built into the camera and it isn't going to work. I can't go to

EL Zone could be mapped and implemented into cameras and monitors, but that would require some work. Above you can see mathematical calculations for various Cinema Log curves. Each one has a different relationship between the Cinemagear Design that stays over the above mentioned false color IRE charts and zones.

Ok, so back to the comparisons. If we look at exposure set to Zone so that there is no overexposure, we can see that the Sony A7S III is at 12 Stops, the Panasonic S1H is at 12 stops and A1 is also at 12/32. This is not how I would recommend exposing this, but I am simply doing this to show you a clear comparison between EL Zone and false color.

If we now switch over to false color I could open the iris up to T2.8 with the S 35/F at 2500 and not get any overexposed or clipped parts of the image. This showcases how much of an additional 6 stops of latitude in the highlights available that weren't being shown if I used EL Zone.

Conversely, if I swapped over to false color with the exact same EI and T stop being used you can also see the dramatic difference between EL Zone and false color. EL Zone was showing parts of the image were already overexposed, while on false color it was showing that I had around 6 stops of latitude in the shadows.

Now, this isn't going to be the case with a lot of cameras because if that actual dynamic range is closer to 12 stops, then EL Zone is a good option to use. But with cameras that are capable of displaying a lot more than 12 stops, it will not be accurate to use EL Zone.

Just to be completely fair to EL Zone, let's look at another camera with less dynamic range to see how it compares. For this example, I will use the Panasonic S1H.

Just like with the V35, I have to change the Color Plan settings to be able to use EL with the Panasonic. In this case, it is **Cinelike D** for the **Color Space** and **-5** stop for the **Curve**.

Once I have made these changes I can then go to my **Exposure Assist** setting and choose **EL Zone**.

Above you can see what it looks like if I set the exposure so that visible grey is correct using EL Zone.

Ok, so the left is how a look at the scene on the S1H with the luminance auto meter exposure tool activated. So you can see it is showing middle grey as being set to 18% (calculated by the 435 DSP).

Above you can see the same image when false color is used instead of EL Zone. Now, please be aware that I have mapped false color on the S1H/FX3 specifically for this example. If you are using false color on a camera like the Panasonic, you can't map false color and that is when you can run into inconsistencies.

Above you can see what it looks like if I set exposure correctly based on EL Zone for middle grey on an 18% grey card.

Let's now check to see how that compares to what I am seeing on the S35's screen when I have false color activated and exposure set to 0 Zone. As you can see, all three exposure methods are giving me almost the exact same result.

Ok, so now let's have a look if I view the exposure so that we get some overexposure in the image. We can see that overexposure is indicated by the color white.

Again, let's see how this compares to what I am seeing on the screen of the S1H and what I am seeing on the S35's screen. As you can see, all three methods are giving the exact same result. I am aware of the image that is showing overexposure on EL Zone is used to refer me that it is 0.5 stops above middle grey. Having worked with the S35 for a long time, I am comfortable with this and I am also aware of what I am looking for. In this case, it is displayed as red which is also indicating overexposure.

From my testing, I found that EL Zone works well with cameras that have dynamic range that is within the limits of what EL Zone is capable of displaying.

When setting exposure it really depends on what you are trying to achieve. In some cases, setting exposure so it looks good for the LUT or Look you are using will be perfectly fine, but in other instances, especially High Dynamic range scenes, you may want to use EL Zone or false color to have the exposure of areas below middle grey, while still seeing your highlights.

Thoughts on EL Zone

I like the concept of EL Zone and in a lot of instances, it works really well. The biggest caveat is that it is limited to showing 12 stops and depending on the camera you are using this can be an issue, especially when displaying accurate overexposure.

On the positive side, it is really nice to be able to see a visual indicator of exactly what is overexposed in the image. This is a big plus for me, as I am very familiar with the S35 and where I usually like to use all of the values it can score in a single display. No, it isn't going to give you 7 stop +/- stop values based on a certain EI or ISO, but it will show you exactly what is clipping and what is not. Being able to see this visually is a big deal and there is value in lower the intensity of a light by a given number of stops. All you need to do is to look at your camera and call out a 1 stop or 4 stop. Because you know what is overexposed, you can be confident that you are not clipping. The issue with EL Zone is showing you that the camera's exposure is 1 stops under when it should be, you know that you will have to either open up the iris to T2.8 or add more light to compensate. For gaffers, they could also have a limited HD monitor with a waveform on the A Cam where they could be seeing the exact same image with the EL Zone applied. This is a big plus for DPs who are working with gaffers.

If a shoot planet is now easy ways of doing things. We have arguably become a used to color forms of technology when dealing with exposure, such as vectras, false color, waveforms, and histograms. EL Zone is a unique way of looking at things and it is another element that can be very useful when judging exposure. Hopefully, in the future, it gets implemented in more cameras and devices, but this will require it to be calibrated specifically to each specific camera sensor and gamma curve.

I'm not working on my old CSI Mac, which is awesome, but I don't see Blackmagic as an option for setting up the color cast and I have a few MA cameras. Does anyone know if ShotPro will be releasing a color cast for Blackmagic?

Thanks for showing this and big thanks to Ed Lachman for creating the system.
I've made an Emag S monitor here in SA a 5% CS Tested loading it on FSI and Arrimoz Blackmagic Cameras and Sony Venice.
https://www.google.com/url?...
Unfortunately it seems to have trouble displaying 0 and 5. You can see my working and tests here: https://www.google.com/url?...
In particular, this tool was helpful for making false colour LUTs for Sony a-series Imagers for Arrimoz: https://colorizer.readio.mu...
Any tips to improve it welcome!

Thanks for the EL Zone is that it isn't just for zone getting "proper" exposure, but it also gives the cinematographer the ability to light for specific contrast ratios without a light meter. You can use it to determine how much contrast you want in a scene. For example, you can set the key exposure at 0 for interior with an exterior visible. Underexpose by 2 or 3, or 4 stops for example, and then light the interior to 0 EL Zone. Now you have a 2, 3 or 4 stop contrast ratio between the key and fill. Or you can overexpose the key by 2 stops. That really is all we need to see. Sometimes we don't need to see the whole range of the scene, we just need to know the key exposure, and more importantly the middle range tone and under 18% grey.

From what I read, the EL Zone will be tailored to each sensor and the zebra system is a great way to represent the extended latitude beyond 12 stops. Although, in most scenarios 12 stops of exposure are more than enough for my purposes.

Fortunately it's not too hard to just make a false color LUT that extends what this tool does to any log curve, for any monitor that supports LUT uploads. I wrote a DCTL for Resolve to generate LUTs with this idea back in February 2022, though I guess I wasn't the first one to think of this.

I am not sure I fully understand what you are saying. But it seems it is a major hurdle that can be overcome. Could you explain a bit more clearly for us with limited knowledge, who are left a bit in the dark?

Thatcher → Peter
16 days ago edited

Here's the updated DCTL:

https://github.com/thatcher...

There are a bunch of instructions in the README in that repository on how to use and install it, but basically the trick is that you apply this downstream of a color space transform to Gamma=Linear, and then you have to find a way to convert this DCTL to a LUT. I provide a couple pointers on how to do that in the Readme as well.

MG → Thatcher
15 days ago

Mark, nice looking DCTLs! I'll take a look. I have indeed built an extended version of EL Zone in ACESproxy log using Nuke. I just need to get around to rebuilding it and exporting it. It requires a pre-transform from other log formats to ACESproxy, obviously. Cameras that already output ACESproxy like some Canon and Sony cams can directly use it, of course.

I guess it's bad mannered of me to allude to how to do it without actually saying how. One way you could do it today would be to use the False Color plugin that comes with Resolve. Shoot an exposure bracket of an 18% gray card and measure the IRE of the card when over/under exposed, and then assign the colors of your choice to those IRE values in that plugin, and bake the result as a LUT. I've got a tool I can use to do something similar, but uses Resolve's color space awareness to not require the exposure bracket step. I'll patch it to let you configure the clipping point and post a link.

Is that limit in the camera software that it's installed on? I don't think that's such a huge problem as lighting to that stop range might be a good idea. It can always be expanded out for different cameras, no?

It does seem to make sense though because he is using more band colours spread out near the skin tone values.

1 0 Reply • Share ›

It could certainly be tailored to individual cameras.

0 0 Reply • Share ›

Jonathon Sendall → Matthew Allard ACS
16 days ago

Agreed. I think the camera manufacturers would need to map their own sensors but it's an excellent application. I would like though to perhaps be able to change the colours as I prefer red as clip, not white.

Its a great tool and far more intuitive than false colour in my opinion. I shoot a lot of Canon (c500ii) and smallHD only has canon Clog as a log option...I have contacted customer service about it as clog is largely redundant with clog 2 and clog3 being the most used for quite some time now. Hoping someone out there from smallHD is listening!!

1 0 Reply • Share ›

Casey → Nick Paton
16 days ago

The C500II has stop based false color built in. 18% grey, one stop over, clipping, and one stop before clipping. It isn't as colorful, but it does most of the job. Use it in combination with the exposure meter and it is easy to get well balanced scenes.

Can do the same thing with customized false color with omniscope/scopebox.
The integration is quite useful tho so that DPs don't need to walk back to their DIT tent when operating.
As for the shoulder and toe of the captured information, pushing one or two stops is normally acceptable for Alexa/Venice cause both their sensor allows and their log curves are quite linear(perceptually linear not mathematically)
however if we are using less capable camera, extreme ETTR/pushing can definitely leads to desaturation and other potential issues such as shot matching. Yes, you can pull it back and the more light CMOS gets the cleaner it is...but anything in the 4+ over zone have a certain degree of information loss.
